Surgical Binocular Loupes by [Surgical](#)

Article published on March 10th 2012 | [Health](#)

Surgical binocular loupes are an essential tool for any physician that has to perform surgical procedures. Surgeons use loupes when it is necessary for them to see a magnified version of what they are working on. They allow doctors to view a small area up close in case they need to see a detailed view of the working area. Many surgeons have come to rely on loupes because they improve their vision so well, that performing without them would actually be a disservice to their patient.

Surgery can be risky for the patient but what many do not realize is that each and every surgery procedure that a doctor does is also a risk to them. Liability insurance is the largest overhead that most physicians face. This insurance protects them from being sued in the case they are found to be negligent.

Surgical binocular loupes are just one more tool that doctors can arm themselves with to make sure that their procedures are done with accuracy and precision. While most people may not be familiar with loupes surgeons are becoming more and more reliant on them. They know that they are becoming more of a necessity because the procedures they are performing today are far more intricate.

A good surgeon will always wear surgical binocular loupes. Those surgeons that do not wear loupes are actually putting themselves and their professional careers in jeopardy. By not being able to see all the details that they need to there is a greater chance of them making a mistake. There is no excuse for doctors not to wear loupes if they are truly an expert in their field.

Surgical binocular Loupe may allow the surgeon to better see the disc herniation. The surgeon always needs to avoid catching the tongue between the teeth and the retractor. Magnification is achieved by surgical loupes, operative microscope, or endoscopy. Outstanding optical quality and optimal focal alignment makes these loupes the perfect choice for dental, surgical, veterinary, jewelry and industrial professionals.

Visualization can then be accomplished directly, with surgical binocular loupes and a headlight, through the operating microscope, or via endoscopy. These systems are thus quite versatile, inexpensive, and easily accessible to most surgeons. The microscopes used in this procedure may be either floor- or ceiling-mounted devices or Surgical binocular Loupe (magnifying lenses mounted on an eyeglass frame) worn by the surgeon. The term microsurgery may also be used to describe the surgical repair of both larger nerves and blood vessels, using custom designed surgical binocular loupes.

Generally the lower magnifications are the most versatile because at the higher magnifications the focal length of the loupe is reduced thereby limiting the working distance between the surgeon and operating field. By simply tilting his head, the surgeon can view the field either through the spectacle lens or through the loupes, thereby allowing him to make use of the magnification only when needed during the procedure. The term microsurgery may also be used to describe the surgical repair of both larger nerves and blood vessels, using custom designed them. One who performs urethroplasty surgery Should purchase a pair of Best surgical binocular loupes, even if one's eyesight is "perfect", Field of loupes comfortably extends the natural accommodation of human eyes
