The Basics on Internet Hosting in Malaysia

by Tracy Narvaez

Article published on February 3rd 2012 | Web Hosting

Malaysia web host refers to the service provided by certain companies in Malaysia, which allows any group wishing to put its operations up on the internet to do so. This is also called internet hosting and is widely popular among established companies and other notable groups like charities and nongovernmental organizations. Hosting involves the offering of space on a server to the client and also provision of internet connectivity.

Depending on the needs of the consumer, there are many methods that are used when it comes to hosting a client. The methods are referred to as applications and range from the very basic to the very large and complex designs. All these will depend to what kind of content is to be put up on the server. The most basic and most commonly featured applications are the simple file transfer protocols and the web page.

There are many web hosting companies in Malaysia. Any of these can be used to request for a web page for which ever cost. A web page incurs little to no expense. Accessing these pages is also very inexpensive or free as in most cases. This browsing is advertisement sponsored, but you have to pay when accessing a business page.

Application development software like java is used for the more complex web pages. These applications which also include cold fusion and other programming tools help in the writing and installing of scripts which aid in content management as well as data base support which is very important. SSL is also vital if you run an e commerce business.

Most large corporations have a need to be online permanently due to the many needs they may have. This takes the form of a computer which is used as the host for the company page. This is then permanently connected to the internet and may be accessed by the public. It contains the details and information about their operations. Clients may also use it to place orders and to communicate with the organization.

In hosting, availability of a web page is important. This is defined as the percentage of time in the year in which a website is up and running and is also accessible by the public. This calculation is done it terms of the up time of the server. Up time is that amount of time which the server or the host computer is online, but not necessarily accessible. The result of the calculation is called the availability of the system.

Every hosting company has scheduled times in the year when the system is down either due to repairs that need to be done or in order for upgrades and maintenance to be done. The total down time is then deducted from the calculated availability and the result is the total availability of the system. If this time is lower than the agreed upon duration between the client and the hosting company, then the client is compensated.

Basically, anyone who wants to set up his own web page should carefully consider the requirements of any plan that he or she decides to go with. The internet access plan you choose should be one which realizes your needs without any extra expenses or baggage. The kind of hosting you choose will depend on your data base, scripting application and your operating system.
